*This brochure has been provided as a courtesy by Gore & Associates (Gore). This brochure will help you learn more about risk factors, common symptoms as well as a less-invasive method of treating a thoracic aortic aneurysm (TAA). Whether you're trying to reduce your risk or supporting a loved one diagnosed with a TAA, we hope this information will be helpful for you and your family.*

## INTRODUCTION

A **thoracic aortic aneurysm (TAA)** is a bulge in the **aorta**, which could **rupture** with life-threatening results. If you or a loved one has this disease, you may be seeking information on how it can be treated. This brochure describes **TAA** and a relatively new way to treat them. One new treatment option is **endovascular repair** using an **endovascular graft**.

For your convenience, we have included a **Glossary of Medical Terms** on page 24 and space in this brochure on page 33 to jot down questions to discuss with your doctor. Words that are **bold** throughout the text can be found in the Glossary of Medical Terms.

This brochure is an informational and referral guide only, and is not intended to diagnose a medical condition. As with any surgery or medical procedure, the best resource for information and advice is your doctor.

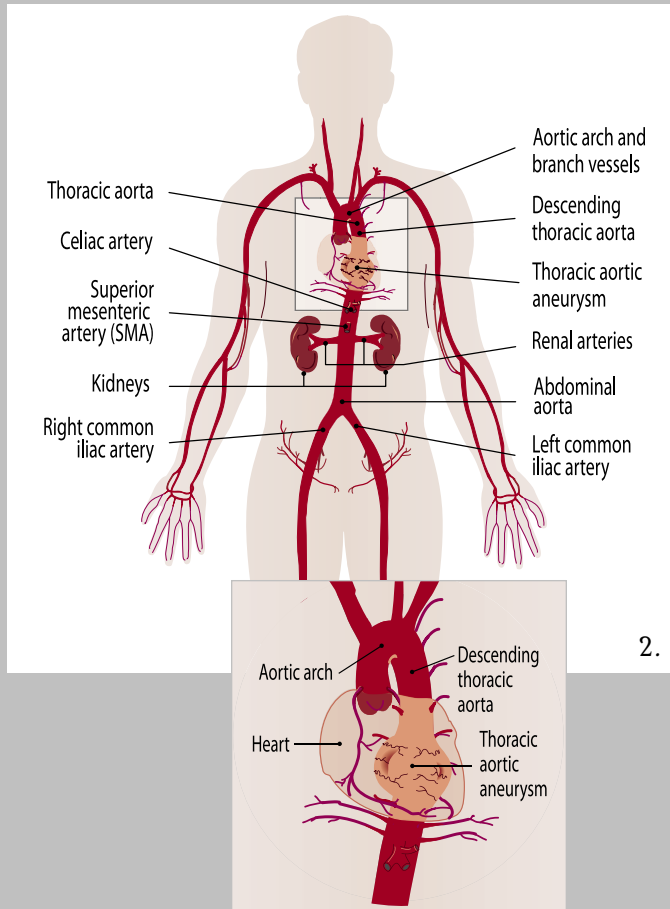

## WHAT IS A TAA?

A **TAA** is the swelling or ballooning of the thoracic aorta. The **aorta** is the main artery that carries oxygen-filled blood from the heart to all parts of the body. In the thorax (chest), once leaving the heart, blood travels upward through the ascending aorta turning into the **aortic arch** branching into the **innominate**, carotid and subclavian arteries.

These branch vessels carry blood to the heart muscle, arms, shoulders, chest, neck, face, and head (including brain). Once past the **aortic arch**, the **aorta** turns downward turning into the **descending aorta** and carries blood to the intercostal arteries, spinal arteries, and ultimately other lower organs and areas of the body (see Figure 1).

*Figure 1 - The **aorta** is the main artery that carries oxygen-filled blood from the heart. It is the largest artery in the body, starting in the chest, with branches into the arm, neck, head, and extending down to the abdomen where it then branches into the **iliac arteries** and into the legs.*

2.

Figure 2 - An **aneurysm** is the ballooning of the thoracic aorta. The weakened sections of the aortic wall may **rupture** (burst).

An **aneurysm** is a ballooning of the **aorta** that results from a weakened section in the artery (see Figure 2).

While the thoracic aorta's diameter normally ranges from 1 to 1.5 inches (2 - 4 cm), an **aneurysm** can cause it to grow to several times its normal size. This condition, if not treated, could result in a **rupture** (bursting) of the **aorta** leading to internal bleeding.

The risk of **rupture** increases with **aneurysm** size and high blood pressure. Ruptured aneurysms are frequently fatal.

## WHAT ARE SOME OF THE SYMPTOMS OF A TAA?

Many people do not experience any symptoms of a **TAA**. Because of this, it is very important to speak with your doctor about your risk of having or developing **TAA** disease. When symptoms do occur, pain is most commonly experienced. This can occur in the chest or back area, shoulders, neck and abdomen. Some patients describe the pain as anything from mild to severe, or a tenderness in the mid or upper chest, back or shoulders. Again, many people may not experience any of these symptoms, yet still be found to have a **TAA**. Your doctor may discover a **TAA** during a routine physical exam. Most often, **aneurysms** are found during a medical test such as a **CT** (Computed Tomography or CAT scan), **MRI** (Magnetic Resonance Imaging Scan) or cardiac catheterization (**angiogram**) procedure.

*Figure 3 - An **angiogram** of a **TAA**.*

Your doctor may also recommend an **angiogram** (see Figure 3), or additional testing such as **CT** (Computed Tomography or CAT scan), **MRI** (Magnetic Resonance Imaging), or **IVUS** (Intravascular Ultrasound) to determine the precise location, size and shape of the **aneurysm** and your surrounding arteries.

## WHAT CAUSES A TAA?

Over time, the weakening of the **aorta** due to vascular disease, injury (trauma), or a genetic (hereditary) defect of the tissue within the arterial wall can cause a **TAA**.

Continuous blood pressure against this weakened area can result in the ballooning (enlarging and thinning) of the aortic artery.

Risk factors for developing an **aneurysm** include heredity (family history), smoking, heart disease, high blood pressure, and high fat diet. Most doctors will advise simple preventative measures such as keeping your blood pressure under control, quitting smoking, reducing cholesterol in your diet and appropriate exercise. These lifestyle changes could also aid in preventing problems in the future.

If you are at risk for developing or have an **aneurysm**, your doctor may recommend periodic screening. This is commonly done with a simple physical exam and possibly a **CT Scan** or **transesophageal ultrasound (TEU)**. Your doctor may also prescribe medication to lower your blood pressure.

## HOW DO DOCTORS TREAT A TAA?

The size and location of the **TAA** and your general health will determine how your **aneurysm** should be treated. When the **aneurysm** is small, your doctor may only recommend periodic check-ups to monitor the **aneurysm**. However, a larger, or rapidly growing (expanding) **aneurysm** poses more risk of bursting (**rupture**), and may require treatment.

Two procedural options are available if your doctor feels treatment is necessary; open surgical repair or **endovascular repair**.

## WHEN TREATMENT BECOMES NECESSARY, WHAT ARE MY TREATMENT OPTIONS?

### MEDICAL MANAGEMENT -

Medical management is the first choice for treatment, including reducing blood pressure and minimizing other risk factors. Medical management usually includes keeping your blood pressure under control, quitting smoking and reducing cholesterol in your diet.

### OPEN SURGICAL REPAIR -

Open surgical repair is an operation to remove the **TAA** when it is considered dangerous and at risk for **rupture**. During this type of operation, the doctor makes an incision (cut) in the chest (front or side) and repairs the **aorta** by replacing the diseased section (**aneurysm**) with a **synthetic graft** (tube) that is sewn into place with sutures.

This procedure requires stopping the flow of blood through the **aorta** while the graft is being put into place. Open surgical repair is typically performed under general anesthesia and takes about 2 to 4 hours to complete. Patients usually spend some time in the intensive care unit (ICU) and another several days in the hospital for early recovery. Depending on how quickly your body heals and any other associated health issues, hospitalization and recovery time may take about 3 to 6 months. Currently, medical management and open surgical repair are standard of care for **TAA** and are proven medical therapies. However, both therapies have their limitations. Medical management does not fix the **aneurysm**, just reduces the stresses (i.e., blood flow pressure) on the **aneurysm**. Although open surgical repair is a proven treatment, not all patients can tolerate this major operation. Ask your doctor about the risks associated with an open procedure as they relate to your overall health condition.

4.

## WHEN TREATMENT BECOMES NECESSARY, WHAT ARE MY TREATMENT OPTIONS? - *continued*

### ENDOVASCULAR REPAIR -

**Endovascular repair** is a relatively new procedure for the treatment of **TAA**. Less invasive than open surgery, it involves excluding (sealing off) the **aneurysm** by placing an **endovascular graft** inside of the diseased **aorta**, re-lining and making a new path for blood flow. The **endovascular graft** (e.g., GORE TAG Thoracic Endoprosthesis) remains inside the **aorta** permanently through the use of a metal stent creating a tight fit and seal against the wall of the **aorta**. **Endovascular repair** may be performed under general, regional or local anesthesia. The procedure typically takes 1 to 3 hours to complete. Patients may have a hospital stay of only a few days and can usually return to normal activity within 2-6 weeks after the procedure.

The endovascular procedure does require regular and routine follow-up visits with your doctor. Tests are performed to evaluate and monitor success of the treatment over time.

Please see the follow-up section on page 20 for further information. Not every patient is a candidate for **endovascular repair**. With this in mind, please check with your doctor to see if you are a candidate. If you would like to learn more about **TAA**, types of therapy, or more information about the GORE TAG Endoprosthesis, visit the websites listed on page 32.

*Figure 4. Artist's rendition of the delivery of a GORE TAG Thoracic Endoprosthesis allowing for endovascular repair of a TAA.*

## WHAT IS THE GORE TAG THORACIC ENDOPROSTHESIS?

The GORE TAG Thoracic Endoprosthesis is an implantable device positioned by a **delivery catheter**. The **endovascular graft** is intended to exclude (seal off), the **aneurysm** by placing the **endovascular graft** inside the diseased **aorta** to make a new path for the blood to flow.

The GORE TAG Thoracic Endoprosthesis is a device that allows for **endovascular repair** of a **TAA**. The **endovascular graft** is a 1-piece, tube-shaped stent-graft that re-lines the **aorta** and extends from as high as the **aortic arch**, to as low as the abdomen above the celiac artery. The GORE TAG Thoracic Endoprosthesis is made of ePTFE (expanded polytetrafluoroethylene), with an outer metallic support structure known as a stent.

*Figure 5 - GORE TAG Thoracic Endoprosthesis*

One or more GORE TAG Thoracic Endoprostheses would be placed in your thoracic aorta. The devices are placed to fit above, across and below the **aneurysm** portion of the **aorta** (see Figures 4, 5 and 6).

Each **endovascular graft** is compressed into the end of a long, thin, tube-like device called a **delivery catheter**. The **delivery catheter** is used to deliver the **endovascular graft** at the **TAA** by making a small incision through an artery in the groin.

Diagnostic measurements (**CT**, **MRI**, **angiography** and **IVUS**) of the **aorta** prior to the procedure allow your doctor to visualize the **aneurysm** and your arteries to select the proper size of **endovascular graft** to fit your anatomy.

*Figure 6 - GORE TAG Thoracic Endoprosthesis (on and off **delivery catheter**)*

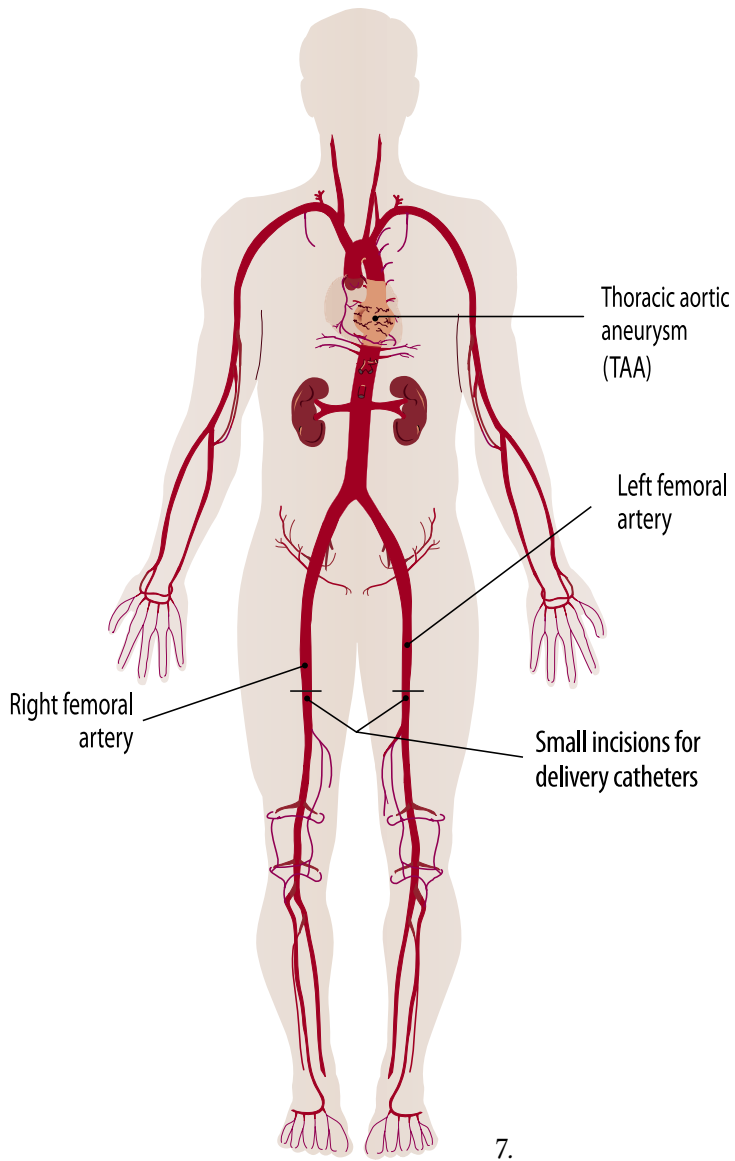

Figure 7 - Insertion sites of **delivery catheters** for placement of GORE TAG Thoracic Endoprosthesis.

## WHAT IS THE GORE TAG THORACIC ENDOPROSTHESIS PROCEDURE?

The GORE TAG Thoracic Endoprosthesis procedure consists of the implantation of a TAG Endoprosthesis to exclude a **TAA**. The **endovascular graft** is implanted using **fluoroscopy** (real-time x-ray images) viewed on a monitor in these steps:

1. A **delivery catheter** is inserted into the **femoral** or **iliac artery** through a small incision (cut) in the groin and carefully guided up the leg artery through the abdomen into the chest (near the heart) to the site of the **TAA** (Figure 7).
2. Once the **endovascular graft** is correctly positioned in the **aorta** (across the **aneurysm**), it is released or deployed from the **delivery catheter**.
3. The device self-expands inside the **aorta** to the diameter of your **aorta**. The placement of the **endovascular graft** is designed to exclude (seal off) the **aneurysm** and reline the artery wall.
4. The **delivery catheter** is withdrawn from the body.
5. Following deployment, an additional step is performed. This step is a ballooning of the device, which aids in sealing/seating of the device in the **aorta**.

8a.

8b.

These steps are the same for each device. At the end of the procedure, your doctor will confirm the position of the device and exclusion of blood flow to the **aneurysm** by using x-ray **angiography** (see Figures 8a and 8b). The doctor will then be able to determine whether the **aneurysm** has been successfully excluded before closing up the incision in each leg with a few sutures.

*Figure 8a - Pre-Op TAA*

*Figure 8b - Post-Op TAA*

*No blood flow to the aneurysm - all blood flowing through the GORE TAG Thoracic Endoprosthesis*

## WHAT FOLLOW-UP EVALUATIONS WILL I HAVE?

Currently, follow-up is advised to include check-ups at 1 month, 6 months, 12 months and annually thereafter. It is very important that you go to all follow-up visits recommended by your doctor.

The follow-up exams will consist of routine x-rays, **CT Scans** and a physical exam. The exams may also include blood tests and **ultrasound** or **MRI** scans if other imaging methods are necessary. These follow-up exams carry some minimal risk, which should be discussed with your doctor. There is a rare risk of allergic reactions related to the **contrast (dye)** used in these **CT Scans**. Please ask your doctor if you have any concerns regarding these tests and exams.

These tests and exams are performed because they are necessary in evaluating the outcome of your treatment and any changes over time. Your doctor may also request additional evaluations based on findings at the follow-up visits. These may include finding a return of blood flow in the **aneurysm** and/or growth of the **aneurysm**. This type and frequency of follow-up visits are generally not required after open surgical repair.

## WHEN SHOULD I CALL MY DOCTOR?

The long-term safety and effectiveness of **endovascular repair** has not been established. Some patients may require additional treatment for conditions such as:

**Endoleak** – An **endoleak** occurs when blood from the **aorta** continues to leak into the **thoracic aneurysm**. While most **endoleaks** do not cause any medical problem, a small number require additional treatment.

**Aneurysm growth or rupture** – Symptoms of **aneurysm** growth are not always present, but when they are, the most common symptom is pain, also numbness, and weakness in the legs, back, chest, or abdomen. **Aneurysm rupture** symptoms include dizziness, fainting, rapid heartbeat or sudden weakness.

**Vessel occlusion** – Symptoms include pain, numbness or weakness in the arm(s), hip(s) or leg(s), or discoloration or coolness of the arms(s), hand(s) or leg(s).

## PATIENT COUNSELING INFORMATION

You and your doctor should review the following risks and benefits when discussing the **endovascular graft** and procedure:

- Risks and differences between **endovascular repair** and open surgical repair.
- Potential advantages of traditional open surgical repair.
- Potential advantages of **endovascular repair**.
- Potential risks of **endovascular repair** including; vascular trauma, **endoleak**, continued **aneurysm** growth, and device movement, etc.
- The possibility that additional endovascular treatment or surgery may be required after initial **endovascular repair**.

In addition to the risks and benefits of an **endovascular repair**, your doctor should consider your commitment and compliance to post-operative follow-up as necessary to ensure continuing safe and effective results.

In such cases, your doctor may recommend outpatient procedures and/or surgery. As with any surgery or medical procedure, there are potential complications with the treatment of a **TAA**. Discuss the risks and benefits with your doctor, and refer to this brochure for basic information. Contact your doctor immediately if you should experience any symptom potentially associated with your **TAA**. Remember, symptoms are not always present, but when they are, the most common symptom is pain, occurring in the chest, back, neck, shoulders or abdominal area.

## GLOSSARY OF MEDICAL TERMS

**Aneurysm** - A ballooning (enlarging and thinning) of a weakened area of a blood vessel.

**Angiography/Angiogram** - A method whereby dye is injected into the bloodstream to view blood flow through the blood vessels under x-ray. Utilizes contrast (dye) and small radiation exposure. The resulting image is an angiogram.

**Aorta** - The main artery that carries blood away from the heart to the rest of the body. It is the largest artery in the body.

**Aortic Arch** - A part of the main artery (aorta) that connects the ascending aorta with the descending aorta. Contains three branches: innominate, left common carotid and left subclavian arteries (see Figure 1).

**Ascending Aorta** - An artery that starts at the origin in the upper surface of the left ventricle (left side of the heart). It passes upward and turns into the arch of the aorta (see Figure 1).

**Catheter** - A slender, hollow, flexible tube that is inserted into the body.

**Contrast (dye)** - A drug injected into the vascular system to show blood flow through the blood vessels on the x-ray image and/or CT scan.

**CT Scan (Computed Tomography Scan)** - A computerized axial tomography scan is more commonly known by its abbreviated name, CAT scan or CT scan. It is an x-ray procedure that often utilizes contrast (dye) and combines many x-ray images with the aid of a computer to generate cross-sectional views and, if needed, three-dimensional images of the internal organs and structures of the body.

**Delivery Catheter** - A long, thin, tube-like tool that assists in the positioning and delivering of an endovascular graft through the vascular system. Also referred to as a catheter.

**Descending Aorta** - The descending aorta is part of the main artery (aorta) that starts at the aortic arch and runs down through the chest and the abdomen. The descending aorta starts after the arch of the aorta and ends by splitting into two great arteries (the common iliac arteries) that go to the legs. The descending aorta, by convention, is subdivided into the thoracic aorta and the abdominal aorta. The thoracic aorta, the part of the aorta that runs from the arch of the aorta to the diaphragm, gives off numerous branches that supply oxygenated blood to the chest cage and the organs within the chest.

**Dilatation** - *The increase in size of a blood vessel.*

**Endoleak** - *Unwanted blood flow into the aortic aneurysm after placement of an endovascular graft.*

**Endoprosthesis** - *See definition under endovascular graft.*

**Endovascular Graft** - *A synthetic graft implanted within a diseased vessel intended to relieve weakened vessel walls without the use of open surgery techniques. Endovascular grafts are delivered to the diseased aorta at a small size and then are deployed or expanded to the size of the vessels in which it is placed. Also referred to as an endoprosthesis.*

**Endovascular Repair** - *Considered to be less invasive than open surgery, it involves the use of an endovascular graft to exclude (seal off) an aneurysm inside a diseased aorta, making a new path for blood to flow.*

*Through this technique, physicians can treat certain conditions through the skin that might otherwise require surgery.*

**Endovascular Treatment** - *The use of real time x-rays and guidewires to treat unhealthy arteries with an endovascular device delivered through small incisions in the iliac or femoral arteries.*

**Femoral Arteries** – Two arteries located in each leg which carry blood to the femoral or thigh region of each leg. Doctors gain access to the iliac arteries and the aorta through the use of the femoral arteries (see Figure 7).

**Fluoroscopy** – A real time x-ray imaging method that helps physicians gain access to the vasculature and guide endovascular devices to their intended treatment area.

**Guidewire** – A long, flexible wire that is placed in an artery to track (or guide) a delivery catheter and other endovascular accessories used to implant an endovascular graft.

**Iliac Arteries** – Two arteries that deliver blood to the legs and connect the aorta to the femoral arteries in each leg. The iliac arteries begin from the bifurcation (separation) of the aorta, which occurs in your abdomen.

**Innominate Artery** – This is the first vessel to branch off the aortic arch. It divides into the right subclavian artery, which provides blood to the right arm and other areas, and the right common carotid artery which supplies blood to the right side of the head and neck (see Figure 1).

**IVUS (Intravascular Ultrasound)** – An ultrasound probe on a delivery catheter placed inside your arteries to see the vessel walls and measure diameters and lengths of your arteries.

**Left Common Carotid Artery** - One of the main branches off the aortic arch that supplies blood to the left side of the head and neck (see Figure 1).

**Left Subclavian Artery** - Provides blood for the left arm and portion of the thoracic area (see Figure 1).

**MRI (Magnetic Resonance Imaging)** - A procedure using magnetic fields and radio waves to form an image of structures inside the body.

**Occlusion** - The blocking of an artery, causing the stoppage of normal blood flow.

**Radiation** - A form of energy that allows your doctor to see blood vessel structures and other anatomy inside your body.

**Rupture** - A tear in the vessel wall near or at the location of the ballooning (enlarging and thinning) of the weakened area of the blood vessel allowing blood to leak into the areas around the heart, lungs or abdomen (hemorrhage).

**Synthetic Graft** - *A man-made material in tube form intended to replace diseased human vessels.*

**Thoracic Aortic Aneurysm (TAA)** - *A ballooning (enlarging and thinning) of the aorta due to a weakening in the arterial wall that occurs in the chest area. This term is often abbreviated as "TAA".*

**Transesophageal Ultrasound (TEU)** - *Transesophageal Ultrasound is a useful tool used to evaluate the function and small detailed structures of the heart and associated vessels.*

**Transesophageal Ultrasound Examination** - *The TEU procedure uses ultrasound waves to produce images of the heart and aorta. Performing a TEU involves passing a tube into the esophagus.*

**Ultrasound** - *An image created through the use of high-frequency sound waves.*
